# 1. Disclosure control by spatial aggregation using quadtrees

European Standard Grid

division

aggregation

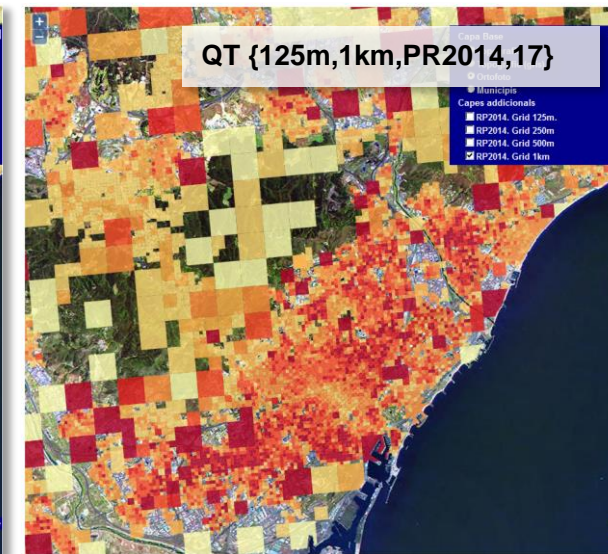

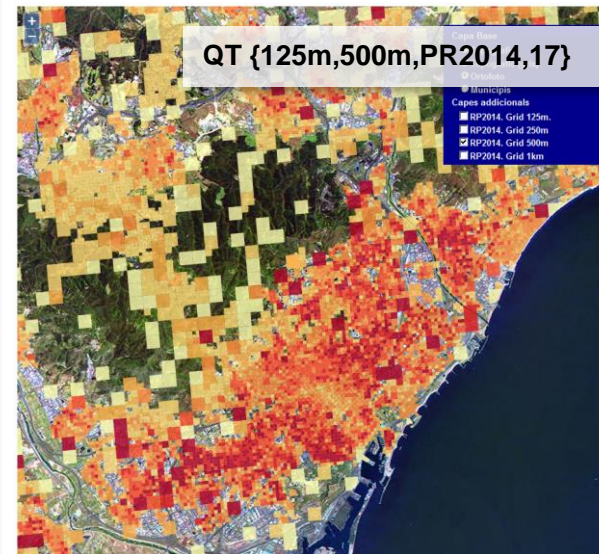

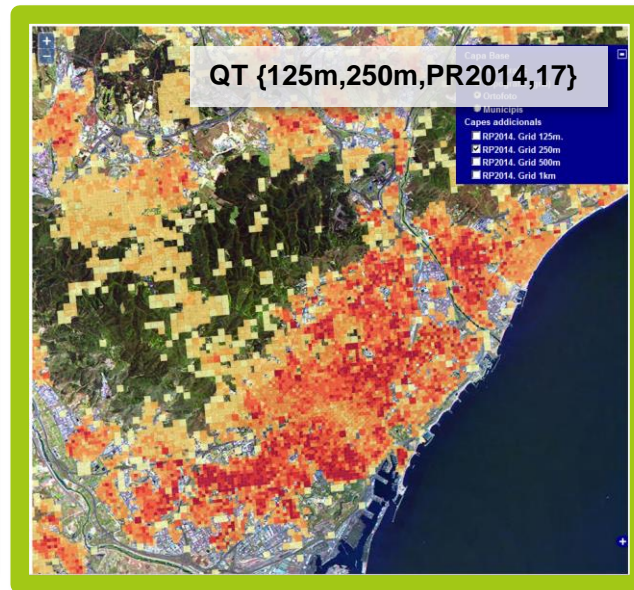

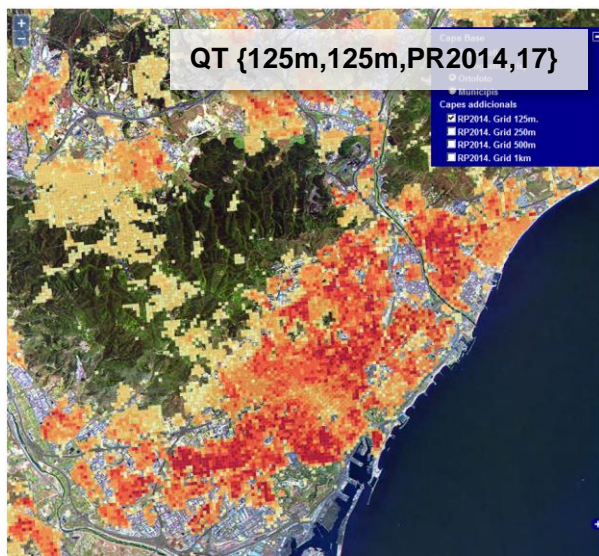

## 2. Quadtree parameters

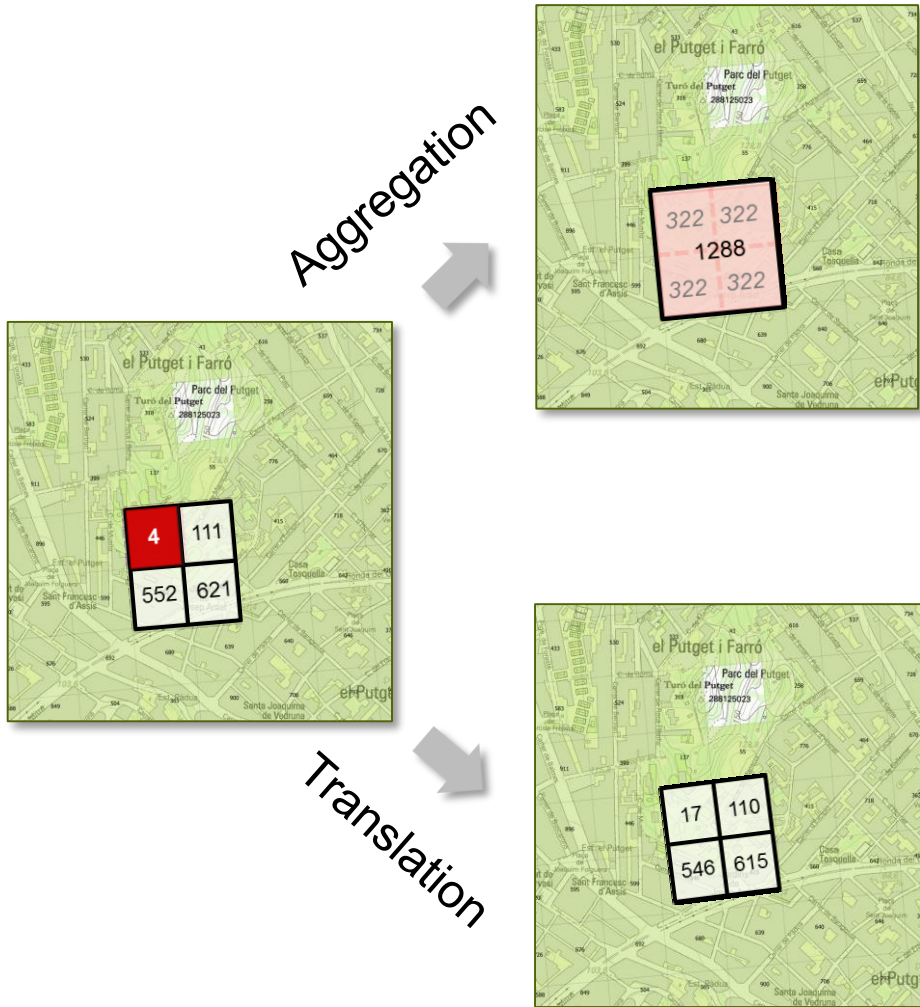

A quadtree is defined by {maximum resolution, minimum resolution, georeferenced data, threshold}

Decision  $\rightarrow$  QT{125m,250m,PR2014,17}

# 3. Border effect. Proposed solution

**Border effect:** undesired aggregation due to high values of the variance

Absolute error when aggregating

$$\epsilon = \sum |n_i - \mu|$$

Can be avoided by **translations** when the absolute error is less than the aggregation

Absolute error when translating

$$\epsilon' = \sum |n_i - n_i'|$$

	% population	
Squares of	Aggregation	Translation
250 m	15.97	3.52
125 m	84.03	96.48
Total	100	100

Only **0.85%** of the total population has been translated

If  $\epsilon' < \epsilon$  it is better to translate

New quadtree with translations:

**QT{125m,250m,PR2014,17,t}**

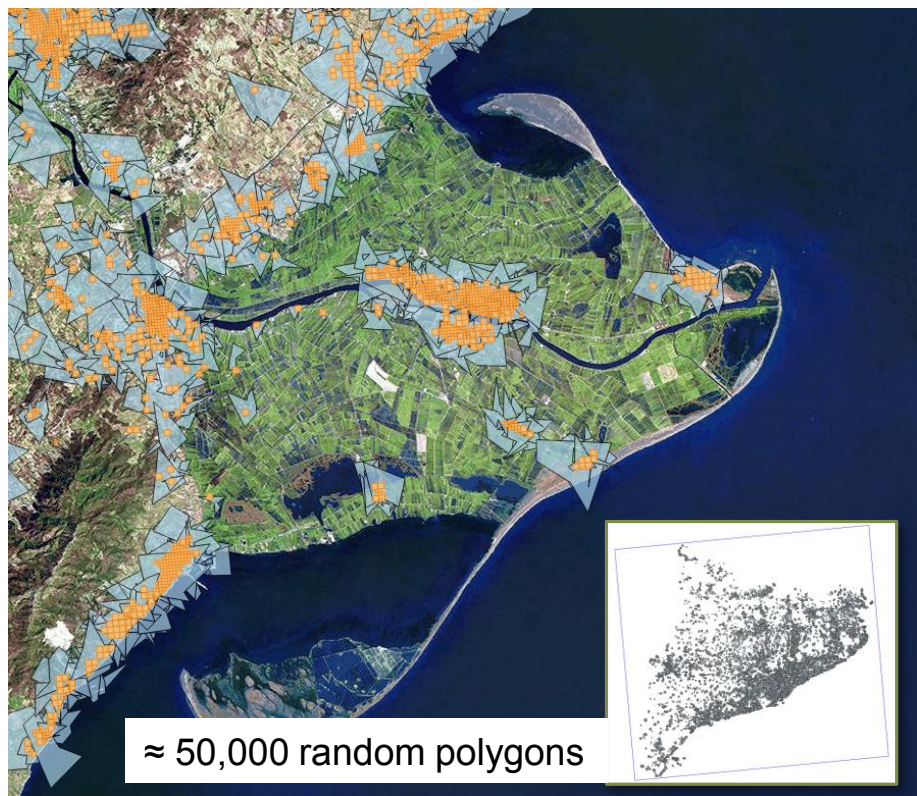

## 4. Errors in population calculations

What is the error when calculating the population within a certain polygon, for example in a flood area, using a quadtree?

# 5. Estimations of errors. Monte Carlo experiment

For each polygon  $S_i$ , relative error is

$$\epsilon_i = \frac{|n'_i - n_i|}{n_i} \quad [1]$$

$n_i$  = Population within the X geometry  $S_i$

$n'_i = \sum n_r * \text{AREA} ( Q_r \cap S_i ) / \text{AREA} ( Q_r )$

	Quartile 1	Median	Quartile 3	Mean
<b>QT{125m, 250m, PR2014, 17, t}</b>	0.02	0.05	0.19	0.28
<b>QT{125m, 250m, PR2014, 17}</b>	0.02	0.07	0.22	0.33
<b>QT{125m, 125m, PR2014, 17}</b>	0.01	0.04	0.14	0.23

**QT{125m,250m,PR2014,17,t}** →

**QT{125m,125m,PR2014,17}** →

## 6. Conclusions

- The use of **quadtrees** for the dissemination of georeferenced data is a good method for the preservation of statistical confidentiality, as a certain balance between security and accuracy is achieved.
- This preservation method may lead to undesirable aggregations in areas which correspond to siblings in the hierarchy, due to the high values of population variance (**border effect**). A solution to the border effect consists of translating microdata under the condition that the absolute error of the aggregation is greater than that of the translation.
- **Monte Carlo** techniques allow the estimation of the relative error distribution for the population calculated within the quadtree structure **QT{125m,250m,PR2014,17,t}**. We have obtained a value of 5.3% for the median of these errors.
